MULTICAST

Refers to the ability of a communications network to accept a single message from an application and deliver copies of that message to many recipients in different locations

PIM SPARSE MODE

We do not forward multicast traffic on any interface until a downstream router requests us to forward it

PIM DENSE MODE

We forward multicast traffic on all interfaces until a downstream router requests us to stop forwarding

PIM SPARSE-DENSE MODE

It allows us to flood the auto RP multicast group 224.0.1.40, but it also floods all multicast traffic for which we don't have an RP

STEP 1

Configure IP for each interface

STEP 2

Configure OSPF network

STEP 3

Enable multicast routing

STEP 4

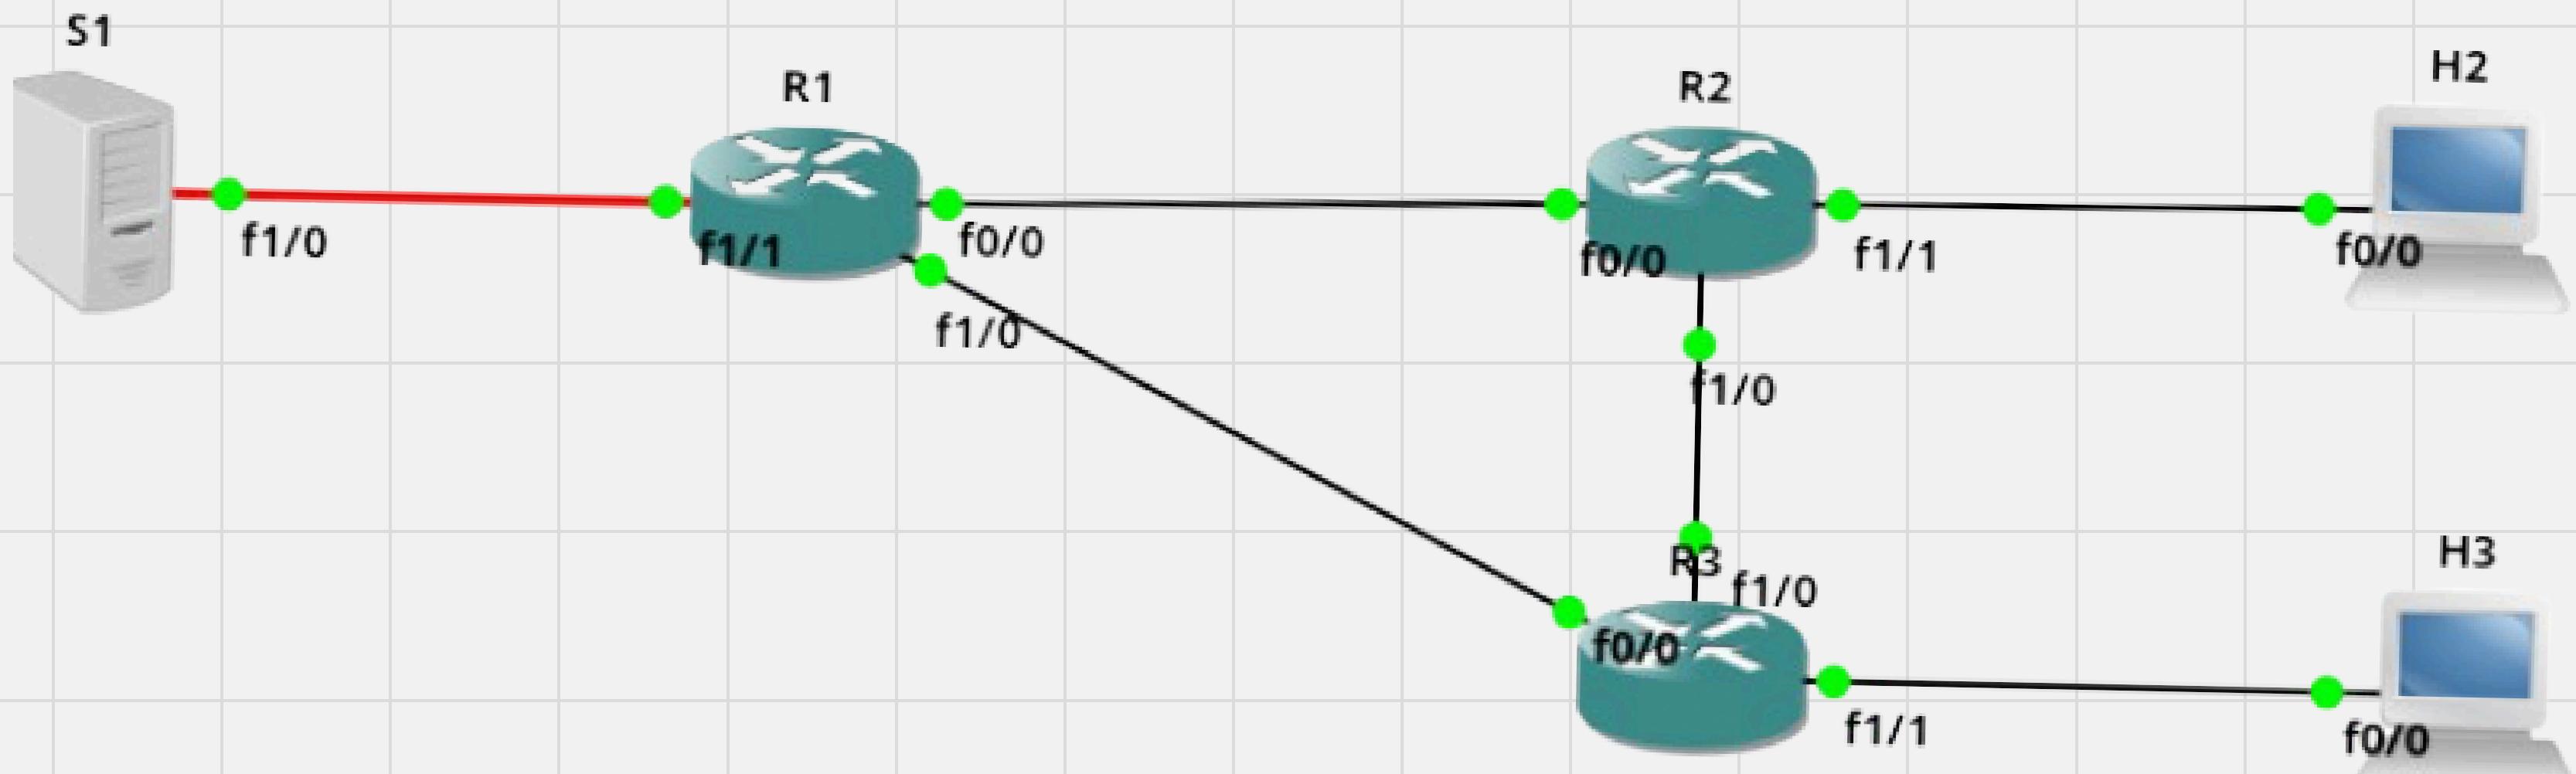

Enable PIM mode and check the neighbors

FIRST STEPS

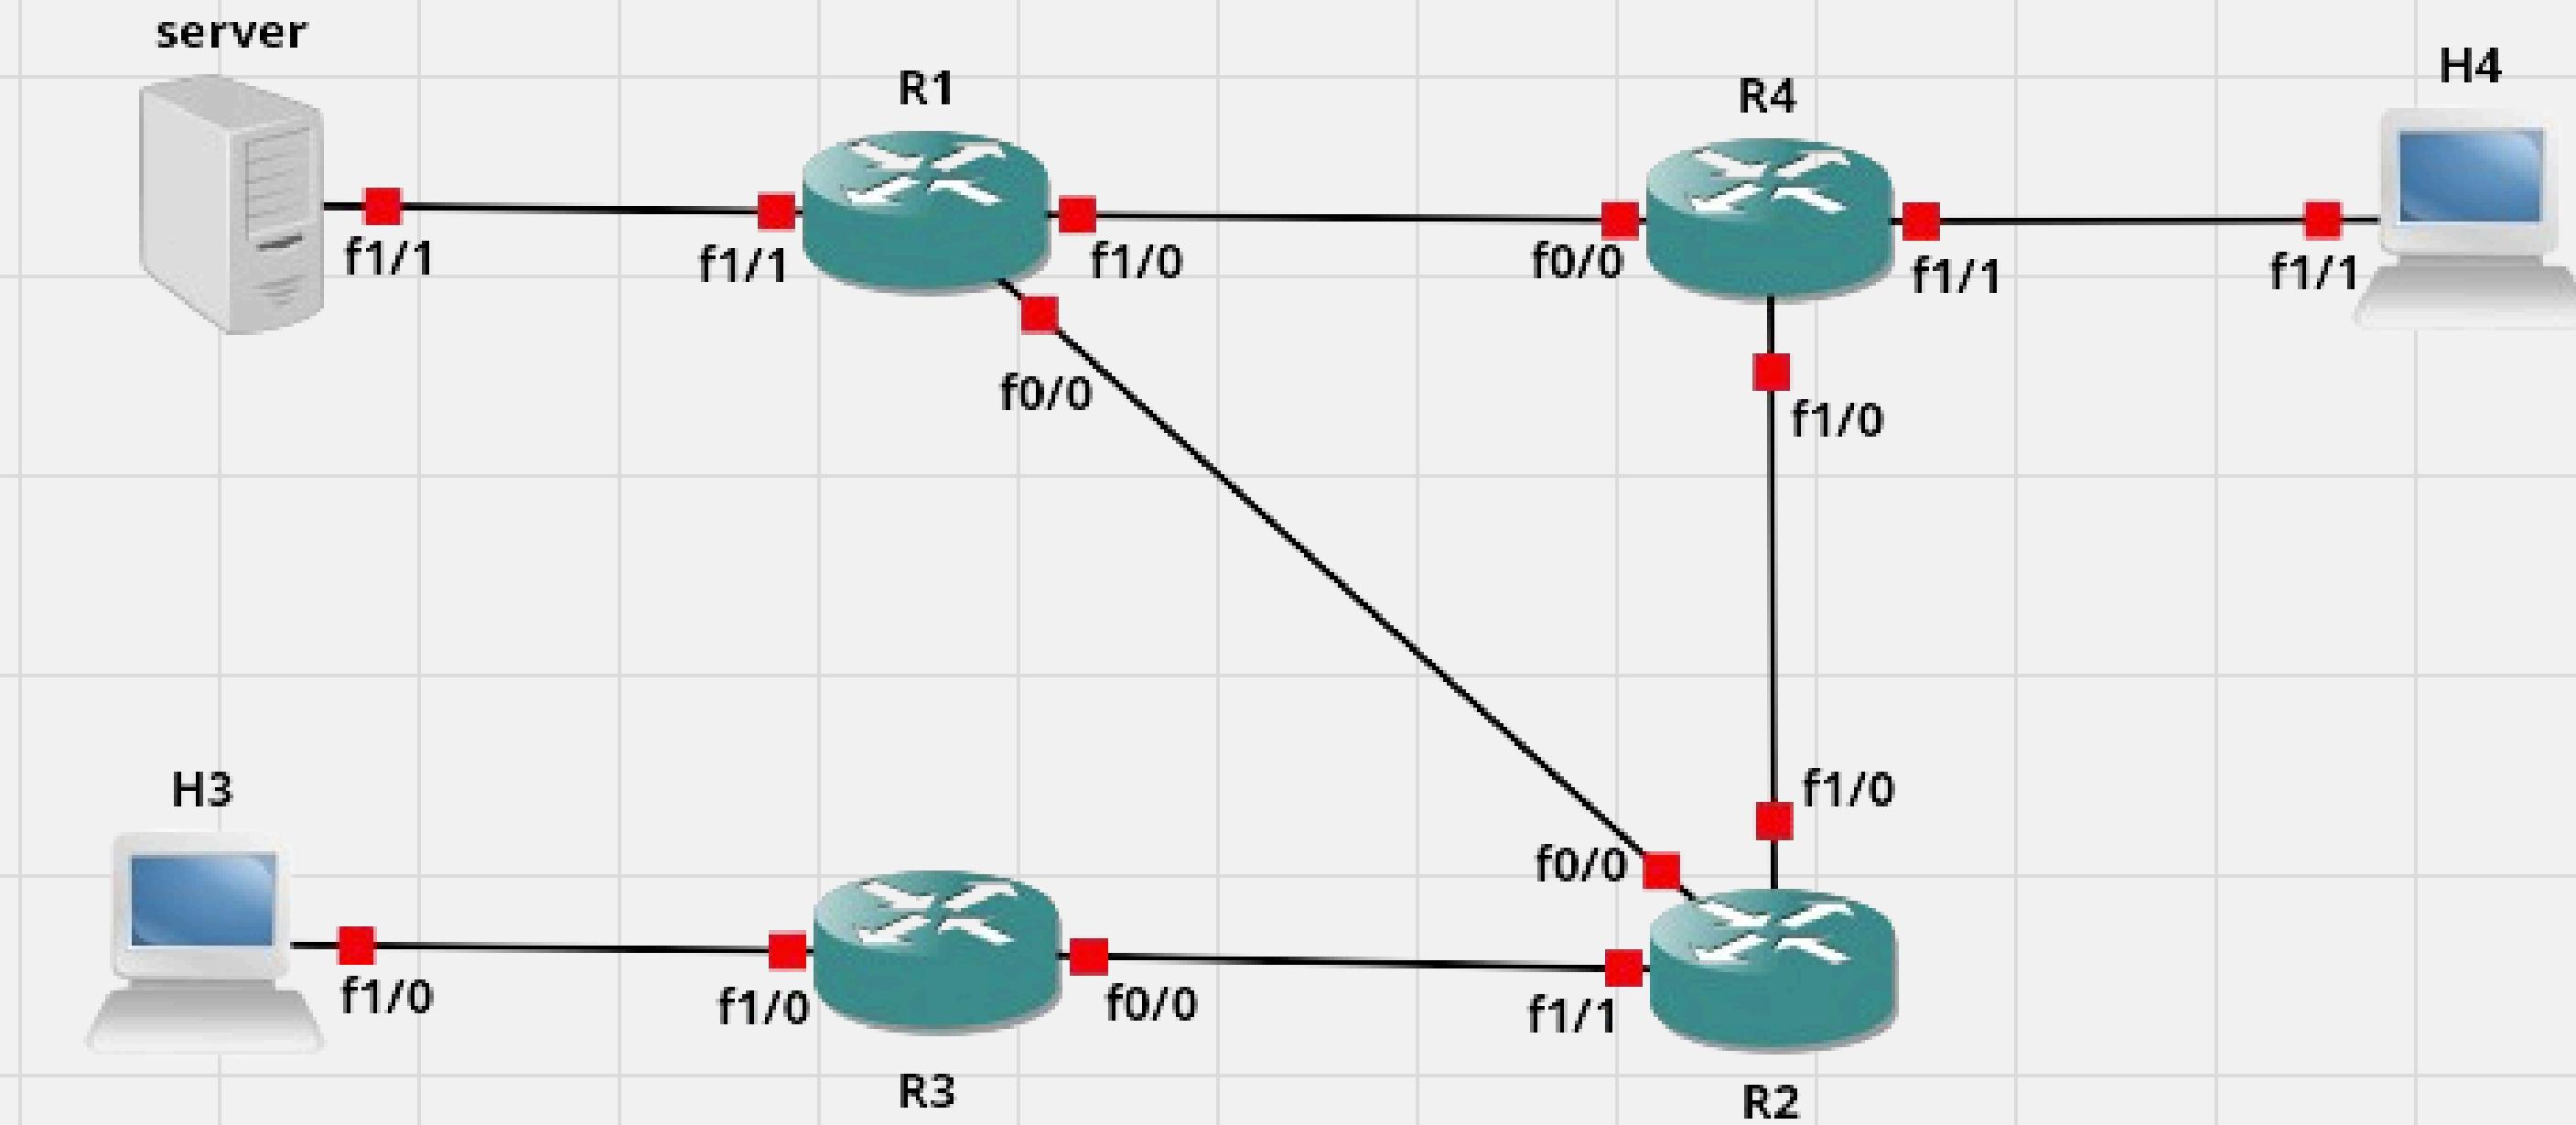

For each PIM mode the first steps are always the same

DEMONSTRATION

CONCLUSION

- **PIM-DM** is optimal for smaller networks with high receiver density due to its proactive traffic forwarding method.
- **PIM-SM** is best for large sparse networks that need to optimize the use of resources.
- **PIM Sparse-Dense Mode** is particularly useful in environments with mixed or dynamic multicast receiver distributions, where resilience and adaptability are critical.
- While PIM-DM excels in simplicity and rapid deployment, it can suffer from inefficient bandwidth utilization. On the other hand, PIM-SM, despite its complex setup and slower start, significantly improves stability and efficient bandwidth usage, drawbacks that are pronounced in PIM-DM.
